You made it! Meteorological winter (December-February) has ended. Cold weather is not entirely behind us, but every sunny day is a longer and brighter day than the day before it. So long and good riddance, 4:40 PM sunsets. There is now twilight past 6:00 PM. We start daylight savings time in just two days. We will lose an hour, but gain sunsets of 7:00 PM or later for the next six months.

How can we best recap our weather for winter 2019-2020? What did CoCoRaHS teach us?

Perhaps one of the most interesting things about winter this year is it seemed to start early. In my last newsletter, I spoke about Colorado experiencing its warmest September on record. Wouldn’t you just know we would have our 3rd coolest October on record? November brought us more of a mix, but some of the best snow of the winter.

Meteorological winter 2020 (DJF), on the whole, may have been shockingly normal for Colorado. We often espouse that “normal” conditions are the blended results of many abnormal years. When precipitation is normal, that’s... a little weird! We still saw our share of spatial variation. This winter was a good one for snow in the northern Rockies. We ended dry in the southwest and northeast corners of the state (figure 2). It’s just about impossible to have normal conditions everywhere across the state. Breckenridge Ski Resort and Copper Mountain recorded their wettest Feburaries on record.
Maps like the one shown above (figure 2) would not be the same without your data. This product, and many others like it, make use of precipitation grids from the PRISM Climate Group. PRISM is possibly our biggest data user. They seek to understand our climate in the most detail possible, and CoCoRaHS precipitation measurements are used heavily in their map-making process.

Best of CoCoRaHS winter 2020

Last year was a big snow year for the mountains. Our biggest “winners” for snowfall were generally in the San Juans (they may not have felt like winners by May). The northern mountains lead the charge on snow this winter. Two of you have eclipsed the 200” of snowfall mark for the season. One in the Steamboat area, and the other on the Grand Mesa. Half of our top ten snowfall observers for the season are in the Steamboat area.

Many of us had a fast start for snowfall this year, eclipsing average snowfall totals for October and November. Our highest 24hr snowfall reports for the year so far came just two days before Thanksgiving, hitting the northern Front Range harder than anywhere else in the state (figure 3). The highest totals were in the foothills just west of our population centers. Several stations west of Livermore, CO received three feet in one day. These are impressive totals, but did you know that the highest verified single day total in Colorado is nearly seven feet?
One interesting aspect of this blizzard was the time of year, just under one month until the winter solstice. This meant the next six weeks would be the six weeks with the least sunlight. Furthermore, water content in the pre-Thanksgiving storm was high. I measured more water content in the snow that day than is normal in December, January, and February combined in Berthoud. For those reasons: 1. High water content, and 2. Short days, it seemed this snow would linger longer than we’re used to. It did. The CSU campus weather station (photo 1) would have measurable snow on the ground for the next 40 days. There are still piles from shoveling on my north-facing front lawn. I estimate I moved one and a half metric tons of snow that morning.
Figure 3: 24-hr northern Colorado snowfall analysis for November 26th, 2019 using CoCoRaHS data.
Long spells of snow cover are normal in the mountains. However, they’re not the norm for the urban corridor. There are a few reasons our snow often melts quickly: 1. Seasonality. For many of us, March is the snowiest month on average. March and April are when we are most vulnerable to blizzards. The sun is also quite bright this late in the snow season, and the days long. It is easy for temperatures to rebound quickly. 2. Chinook winds. When storms track across a mountain range the air does some interesting things on the downwind side. It will often a) accelerate due to gravity as it flows down the mountainside, and b) warm up through compression. These fast-moving, warm winds have been known to eat as much as a foot of snow cover in one day. It would be fun to explore chinooks in more detail. Maybe next time. 3. Cloud cover. Even in winter, Colorado usually has much sunnier weather than other snowy parts of the county (e.g. Northeast and Upper Midwest). We aren’t strangers to wintry skies, but these conditions don’t often last for days on end.

Colorado was subject to another impressive snow event in the first half of February. Steamboat Springs received over 30” of snowfall over the 5-day period from February 6th to 10th. Other parts of the northern Rockies from Garfield to Summit County also fared quite well. Glenwood Springs stations recorded upwards of two feet over the same time frame. While it was more of a mountain event, snow totals on the urban corridor did outperform the forecasted values.
On the morning of Monday, February 24th I went through my normal routine of walking the dog, feeding the dog and cat, and then checking the rain gauge. This morning I was saddened to see that no snow had fallen overnight, despite an expectation of an inch or two. It had snowed down near the Palmer Divide on Sunday, but the snow had missed me. Not but two minutes after checking my gauge, I received a “snow squall warning” on my phone from the National Weather Service forecasting office in Boulder. Sure enough, it began to snow hard. The snow produced near-whiteout conditions for the better part of 10 minutes, and then just like that, it was over. The accumulation was only 0.03” of precipitation, and 0.5” of snowfall. It was lucky I was still home to observe the accumulation as winds continued to howl for hours after the snow. The ground quickly dried.

Snow squalls are not new, but this warning system is. The National Weather Service in Boulder just began issuing snow squall warnings this winter. Their explanation is given in the infographic below.
I cannot speak for the weather service, but in my experience, the reactions of people to these new warnings has been mixed. For many, the alerts seem welcome, perhaps even novel or exciting. I have also spoken with several folks who feel as though this is a waste of our emergency broadcast system. To their credit, a snow squall is unlikely to have consequences if you aren’t traveling. What’s so bad about a short burst of snow while sitting in your office chair at work? It is easy to see how warning a squall could be viewed as “crying wolf.” However, snow squalls have been proven to rapidly reduce visibility, degrade road conditions, and catch drivers unaware. This is a dangerous combination; one that results in accidents and fatalities. Communicating such hazards to us in a timely and clear manner, so accidents and fatalities do not occur, is manifestly a part of the National Weather Service’s obligation to taxpayers.

What should you do if you receive a snow squall warning while driving? The short answer is to be careful and use common sense. Often times our schedules aren’t very flexible, so you may feel as though you have limited capacity for avoiding the danger. But do keep in mind that snow squalls are typically short-lived. If your schedule allows for it, stop for a bite to eat or a cup of joe until the warning has expired. The worst danger will likely pass soon. Afterall, we plan accordingly when warned of a blizzard or severe thunderstorm. Is this approach so different?

**March Recruiting Drive**

Some of you may have noticed that March is an important month for CoCoRaHS. This is the time of year where we conduct a national recruiting effort. Drives like these are instrumental in ensuring our long-term success. As always, we need your help. High pressure sales pitches are not my forte, just please consider doing the following: Next time it rains or snows, and you enter a conversation about the storm, consider sharing your CoCoRaHS experience. You can always send your inquisitive friends my way for more information.
More importantly than anything, thank you so much to each and every one of you who have made this quirky network a part of your routine. You make the CoCoRaHS family much more special than we could have dreamed 25 years ago.
